

Peripheral Catheter Securement Devices

All central vascular access devices should be stabilized to prevent complications such as device movement or pistoning in the vessel that may cause phlebitis, cause the introduction of microorganisms into the vessel, and/or unintentional loss of venous access. The methods used to stabilize a device should not interfere with the assessment or monitoring of the site and should not impede vascular circulation or delivery of the prescribed therapy. Vascular securement can be grouped into 3 primary categories: sutures/staples, subcutaneous anchoring device, and cutaneous/adhesive based securement devices. Below is an overview of the securement and stabilization devices available on the market. You may click on the product links, where available, to learn more about the manufacturer and device.

Medical-Grade Glue (Cyanoacrylate)
